Console Filtering (Filter by Text)

Console filtering lets you search and display only specific log messages using keywords or tags. This makes it easier to find important information without scrolling through everything. It is useful for debugging because you can quickly focus on relevant logs like [ERROR], [ACTION], or [PERF].

performance.mark()

places a timestamp at a specific point in your code. It helps you track when something starts or ends, like a user action or game event. This is important because it lets developers break down performance into smaller steps for more detailed analysis.

performance.measure()

calculates how long something takes by measuring the time between two marks. It gives you a duration value (in milliseconds) so you can see how fast or slow an operation is. This is important for identifying slow parts of your program and improving performance.
